

SHC Vancomycin Dosing Guide

- A: Initial dosing considerations
- B. Pharmacodynamic Targets: goal AUC and troughs
- C. Loading dose
- D: Initial Vancomycin Maintenance Dosing and Serum Concentration Monitoring
- E: Dose Revisions
- F: Intermittent Hemodialysis Dosing Algorithms
- G: PK equations

A. Initial Dosing Considerations

1. Review the following prior to initiation of therapy:
 - a. Indication, relevant and pending microbial culture(s)
 - b. Age, gender, height, weight, BMI
 - c. Renal replacement therapy
 - d. Special populations (obese, elderly, severely malnourished [BMI<16], amputees, pregnancy)
 - e. Prior vancomycin dosing history (if applicable)
 - f. Potential drug interactions
 - g. Serum creatinine (SCr), urine output (if available), creatinine clearance (CrCl)
 - i. Calculate CrCl using the Cockcroft-Gault equation (Figure 1)
 - a) Elderly or severely malnourished: rounding SCr up is associated with underestimation of CrCl- clinical discretion advised [Smythe 1994, Young 2017, Barber 2016, Winter 2012]
 - b) Use ideal body weight (IBW) for non-obese patients
 - c) Use adjusted body weight (ABW) for obese patients [total body weight (TBW) $\geq 20\%$ of IBW or BMI ≥ 30 kg/m²]
 - d) Use total body weight (TBW) if TBW < IBW

Figure 1. Cockcroft-Gault Equation

$CrCl \left(\frac{ml}{min} \right) = \frac{(140 - age) \times IBW \ (x \ 0.85 \ for \ females)}{SCr \times 72}$	<p>IBW (male) = 50 kg + (2.3 x height in inches > 60 inches)</p> <p>IBW (female) = 45 kg + (2.3 x height inches > 60 inches)</p> <p>ABW (kg) = IBW + 0.4 (TBW – IBW)</p>
--	--

- h. Adverse Effects
 - i. Red Man Syndrome is characterized by hypotension and/or a maculopapular rash appearing on the face, neck, trunk, and/or upper extremities.
 - ii. If this occurs, pharmacist may slow the infusion rate (e.g. to 90-120 mins per 1 gm.) \pm increase the dilution volume upon provider request \pm recommend diphenhydramine 25-50mg premedication to the provider

B. Pharmacodynamic Targets: goal AUC and troughs

Indication	Target PD Index
Most indications	
AUC-based protocol	AUC 400-700
Trough-based protocol (dialysis, dose-by-level)	Trough ~15 (10-20)
Meningitis (empiric or definitive)	
MRSA infections with vanco MIC = 2	
AUC-based protocol	AUC 600-800
Trough-based protocol (dialysis, dose-by-level)	Trough 15-20
<ul style="list-style-type: none"> In general, goal AUC/MIC ≥ 400 for <i>S.aureus</i> Monitor closely with trough > 15 or AUC > 700: increased risk of nephrotoxicity Vancomycin may be continued in clinically responding patients with MRSA w/vancomycin MIC = 2 	

Exclusions from AUC-based dosing: rapidly fluctuating SCr, AKI (see section D footnote), renal replacement therapy

C: Loading dose

I. Purpose:

Ensures (Area Under Curve)/(Minimum Inhibitor Concentration) of >400 mcg-h/mL is achieved on day 1 of therapy for bacterial killing in in vitro and clinical outcomes in vivo studies

II. Targeted populations:

- Preferred in seriously ill (e.g. severe sepsis or septic shock requiring coverage for *S. aureus*)

III. Standard load for patients with normal renal function: 25-30mg/kg TBW

Patient Weight	Standard Loading Dose ~25 mg/kg TBW	Modified Loading Dose 15-20 mg/kg TBW Obese (BMI ≥ 30) CrCL < 30 or AKI, IHD, CRRT, unavailable Scr in emergent situations (e.g code sepsis or ED)
36 – 45 kg	1,000 mg x 1	750 mg x 1
46 – 55 kg	1,250 mg x 1	1,000 mg x 1
56 – 65 kg	1,500 mg x 1	1,250 mg x 1
66 – 75 kg	1,750 mg x1	1,500 mg x 1
76 – 120 kg	2,000 mg x 1	1,750 mg x1
> 120 kg	2,000 mg x 1	2,000 mg x 1

*Time maintenance dose start based on renal function: e.g. wait 24h to start maintenance regimen if CrCl = 30
Use total body weight (TBW); Round doses to nearest 250mg. Infuse each 1000mg over 60 minutes.

D: Initial Vancomycin Maintenance Dosing and Initial/Repeat Monitoring

- I. **Round** doses to nearest 250mg
- II. **Maximum dose:** 2gm per dose and 4.5g per 24h initially (including load)
- III. **Repeat Vancomycin Levels**
 - A. After the target AUC or trough level is achieved at steady state, trough levels should be checked every 2 to 5 days until completion of therapy or discharge. Check peak/trough after any dose initiation/change.
 - i. Levels should be checked sooner when clinically warranted (i.e.: change in clinical status or renal function, concern of accumulation/supratherapeutic levels, $\geq 25\%$ change in trough/SCr)
 - B. If follow-up trough is within expected range, the AUC is likely within range as well
 - C. If follow-up trough is outside expected range, obtain another level to recalculate AUC
 - D. Troubleshooting: if a level is missed, draw level with the next dose if at steady state. Otherwise, re-send new paired peak/trough
- IV. **Repeat SCr:** q1-3 days if hemodynamically stable. Check daily if at high risk of nephrotoxicity.
- V. **Can calculate an estimated total daily dose using PK equations (see Part G) or use the table below**

Creatinine Clearance (mL/min)	Dose & Frequency Total body weight (TBW)	TDD Range	Timing of Peak/Trough Levels
> 90	15 mg/kg Q8-12H BMI ≥ 30 : 10 – 15 mg/kg TBW Q12H [†] BMI ≥ 40 : 7.5 – 12.5 mg/kg TBW Q12H [†]	30 – 45 mg/kg/day Obese: 15 – 30 mg/kg _{TBW} /day	Peak 1hr after 4 th / trough 30 min before 5 th dose, or Peak 1hr after 3 rd / trough 30 min before 4 th dose
51-89	10– 20 mg/kg Q12H BMI ≥ 30 : 10 – 12.5 mg/kg TBW Q12H [†] BMI ≥ 40 : 7.5 – 10 mg/kg TBW Q12H [†]	20– 40 mg/kg/day Obese: 15 – 25 mg/kg _{TBW} /day	Q12H: Peak 1hr after 4 th / trough 30 min before 5 th dose, or Peak 1hr after 3 rd / trough 30 min before 4 th dose
30-50	10-15 mg/kg Q12H to 20 mg/kg Q24H	20 – 30 mg/kg/day	Q12H: as above Q24H: Peak 1hr after 3 rd / trough 30 min before 4 th dose
10-29	10 – 15 mg/kg Q24H to 15 mg/kg Q48H	7.5 – 15 mg/kg/day	Q24H – Peak 1hr after 3 rd / trough 30 min before 4 th dose Q48H – Peak 1hr after 2 nd dose; trough 30 min before 3 rd dose
<10 or AKI*, dose by level	15 mg/kg x1, then dose by level	N/A	Trough within 24 hours of last dose, or with AM labs or every other day
Hemodialysis	<u>Initial:</u> 15 – 20 mg/kg x 1 (max 2gm) <u>Maintenance:</u> see appendix E	N/A	<ul style="list-style-type: none"> Single pre-dialysis level (preferred) Alternative: single level 4 hours after completion of dialysis session
CRRT[‡]	<u>Initial:</u> 15 – 20 mg/kg x 1 (max 2gm) <u>Maintenance:</u> 10 – 15 mg/kg Q24H	N/A	Trough 30 min before 3 rd or 4 th dose
Peritoneal dialysis	10 – 15 mg/kg IV x1, then dose by level	N/A	Check level 24h after initial dose. Consult ASP
	Dosing for intraperitoneal (IP) instillation (<i>NOT part of protocol</i>) [Li, 2016] Intermittent (1 exchange/day): 15-30mg/kg IP initially, then dose by level* *supplemental doses may be needed for APD patients		Intraperitoneal dosing (<i>off-protocol</i>): Level with AM labs on day 3 after any dose administered (allow fluid redistribution before drawing random level)

[†] Note: For those with CrCL_{adjBW} > 120mL/min, Q8H may be considered if t_{1/2} < 8hr**

[‡] Loading and maintenance doses are based on 1-2L/hr dialysate flow and ultrafiltration rates, which is estimated to mimic a creatinine clearance of 30-50 mL/min

***AKI (based on KDIGO, RIFLE, AKIN classifications):**

- i. SCr change by ≥ 0.3 mg/dL within 48h or 50% from baseline or within last 7 days
- ii. CrCl change by $>25 - 50\%$
- iii. Urine output < 0.5 mL/kg/hr over 6 hours (oliguria)

****Calculating t_{1/2} in obesity**

Step	Equation (adjusted for obese)
1	CL _{vanco} = CrCL _{adjBW} x 0.06 (see right table)
2	V _d = (0.5 – 0.7, see right table) x TBW
3	k = CL _{vanco} /V _d
4	t _{1/2} = 0.693/k

Modified CL _{vanco}	
BMI ≥ 40 kg/m ²	max CL ~7
Modified V _d	
BMI 30-40 kg/m ²	~0.7 L/kg
BMI ≥ 40 kg/m ²	0.5 – 0.6 L/kg

E: Dose Revisions

AUC calculator: This calculator is based on the Sawchuk-Zaske method and the equations used are summarized here.¹¹ Click [here](#) for link to AUC calculator on Microsoft Excel.

$$AUC = \frac{t (C_{max} + C_{min})}{2} + \frac{C_{max} - C_{min}}{k}$$

$$t = \text{infusion duration}, k = \frac{\ln \frac{C_1}{C_2}}{\Delta t}$$

- This AUC value applies to that calculated in a single dosing interval $\Delta t \rightarrow$ must be multiplied by the dosing frequency when applicable to obtain the total AUC₀₋₂₄
- C_{max} (true peak) and C_{min} (true trough) are back-calculated from measured values using this equation:
 $C_2 = C_1 \times e^{-k t}$. (Details are in Part G)

Fig. 5. Expected area under the curve captured using Eq. (4) based on an expected vancomycin concentration time profile.

Linear proportion method: Once a calculated AUC or trough is obtained, changes to the total daily dose (TDD) have a corresponding proportional change in troughs and AUCs when maintaining the same dosing interval, **assuming stable renal function and steady state conditions**.

$$\frac{AUC \text{ (calculated)}}{AUC \text{ (desired)}} = \frac{\text{Current TDD}}{\text{New TDD}}$$

$$\frac{C_{min} \text{ (observed)}}{C_{min} \text{ (desired)}} = \frac{\text{Current TDD}}{\text{New TDD}}$$

E.g.: 1250mg IV Q12H results in an AUC of 800. To target a AUC 600, reduce to 1g q12h (rounded up from 1875mg/day). Alternatively, converting the same TDD to a q8h regimen would result in a higher trough but would not impact the AUC.

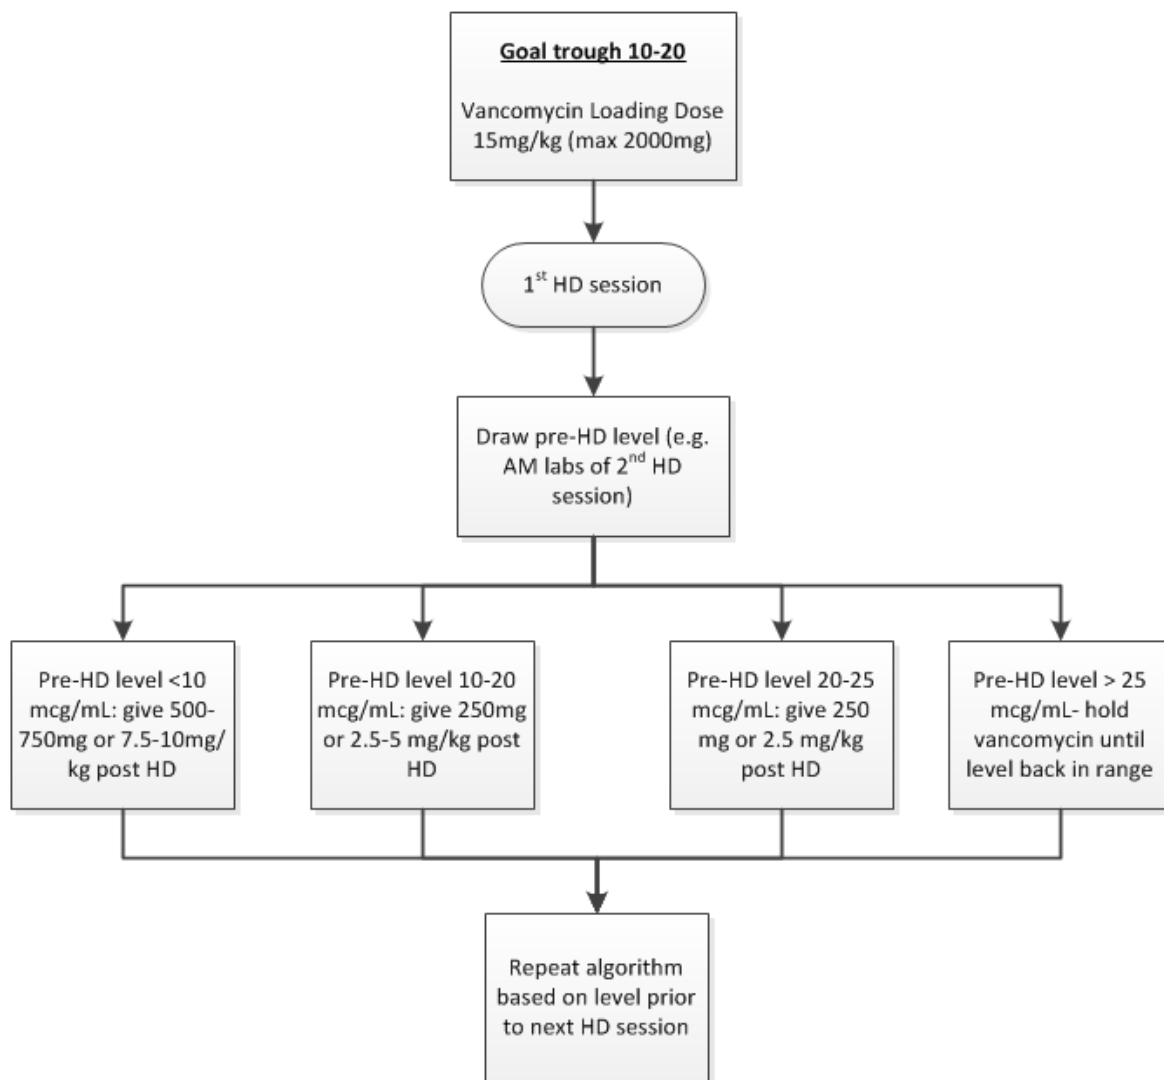

$$\text{New TDD} = \frac{600 \times 2500\text{mg}}{800} = 1875\text{mg}$$

Supratherapeutic levels and/or AKI: general approach

- Do not restart vancomycin until the random/trough level is estimated or confirmed to be at/near 10-20 mg/dl. Allow sufficient time for drug clearance before restarting next dose.
- Actions may include: pre-emptive dose adjustment, holding dose, checking level, discussion with provider, reassessing the need for vancomycin therapy.
- Consider SCr/renal trajectory when determining next dose and/or level
 - Ex) rapidly declining Scr may indicate improving renal function warranting earlier redosing vs. rapidly rising Scr indicating ongoing AKI- dose by level may be indicated

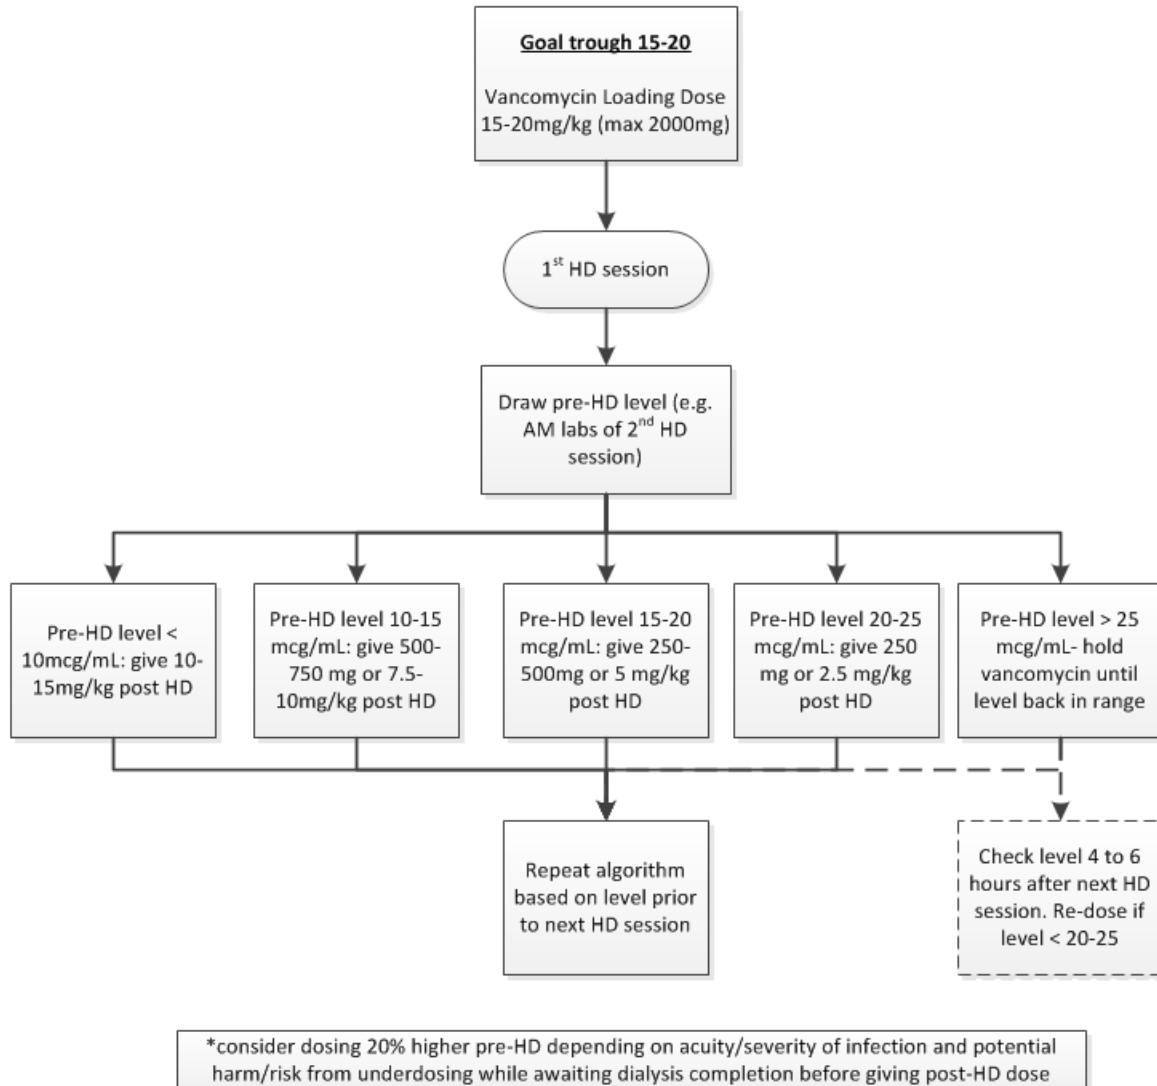

F: Intermittent Hemodialysis Dosing Algorithms

For goal trough 10-20 mcg/ml (~15):

*consider dosing 20% higher pre-HD depending on acuity/severity of infection and potential harm/risk from underdosing while awaiting dialysis completion before giving post-HD dose

For goal trough 15-20 mcg/ml:

G: PK Equations (same as those used in SHC Vancomycin Excel AUC Calculator)

AUC-based dosing: initial dosing

1. Step 1: estimate CL_{vanco} (L/hr) = $k_e \times V_d$
 - a. In general populations: Matzke Equation: $k_e = 0.00083 \times CrCl + 0.0044$
 - b. In obese patients: Crass et al 2018: $CL_{\text{vanco}} = 9.656 - 0.078 \times \text{age} - 2.009 \times SCr + 1.09 \times \text{sex} + 0.04 \times TBW^{0.75}$, where female = 0 and male = 1.
 - i. Reference: doi:10.1093/jac/dky310
2. Step 2: estimate total daily dose = $CL_{\text{vanco}} \times \text{goal AUC}_{0-24}$

AUC-based dosing: revision from 2 levels

Step	Description	Equation
1	Verify that doses were given on time and drawn appropriately	
2	Calculate the patient's observed k_e from 2 levels	$k_e = \frac{\ln \frac{C_1}{C_2}}{t_2 - t_1}$ where C_1 usually is the peak, C_2 is usually the trough
3	Calculate half-life, $t_{1/2}$	$t_{1/2} = \frac{0.693}{k}$
4	Calculate true peak, C_{max}	$C_{\text{max}} = \frac{C_1}{e^{-k \Delta t}}$, Δt = time between end of infusion and time level drawn
5	Calculate true trough, C_{min}	$C_{\text{min}} = C_{\text{max}} \times e^{-k_e \times (\text{tau} - t)}$ where t = infusion time
6	Calculate V_d (steady state conditions) <i>*optional step: not required to determine AUC</i>	$V_d = \frac{\text{Dose} \times (1 - e^{-k \cdot t})}{t \times k_e (C_{\text{max}} - [C_{\text{min}} \times e^{-k \cdot t}])}$ where t = infusion time
7	Calculate vancomycin clearance <i>*optional step: not required to determine AUC</i>	$CL_{\text{van}} = V_d \times k_e$
8	If C_{min} is high, calculate the time needed to reach desired range	$\text{Time for } C_{\text{min}} \text{ to reach } C_{\text{desired}} = \frac{\ln \frac{C_{\text{min}}}{C_{\text{desired}}}}{k_e}$
9	Calculate AUC during infusion using linear trapezoidal rule	$AUC_{\text{inf}} = t \times \frac{(C_{\text{max}} + C_{\text{min}})}{2}$
10	Calculate AUC during elimination using logarithmic trapezoidal rule	$AUC_{\text{elim}} = \frac{(C_{\text{max}} - C_{\text{min}})}{k_e}$
11	Calculate AUC_{24}	$AUC_{0-24} = (AUC_{\text{inf}} + AUC_{\text{elim}}) \times \frac{24}{\text{tau}}$
12	Estimate total daily dose need to achieve target AUC_{24} <i>Tip: new tau = 1 to 1.5x the half-life</i>	$\text{New TDD} = \text{Current TDD} \times \frac{AUC_{0-24} (\text{desired})}{AUC_{0-24} (\text{calculated})}$
13	Calculate predicted steady state C_{max} for new dosing regimen	$C_{\text{ss,max}} = \frac{\text{New dose}}{CL \times t} \times \frac{1 - e^{-k \cdot t}}{1 - e^{-k \cdot \text{tau}}}$
14	Calculate predicted steady state C_{min} for new dosing regimen	Same as step 5
15	Calculate predicted AUC based on new dosing regimen	Same as steps 9-11
